Liniar Roof Structural Guide
Issue 2.3, March 2017

Introduction & Contents

For specifications beyond this guidance contact the Liniar Roof Technical Department.

Introduction...

The guidance calculations detailed in this document assess the structure of the conservatory roof, it assumes and assume that the fabrication and installation is carried out in accordance with the Liniar roof current fabrication & installation manuals.

We have provided this information in a series of easy to read tables, illustrating the span capabilities of your individual roof pitch and rafter roof bar spacings.

Please ensure that when using this guidance document all the loading bearing elements, i.e. Eaves Beam, Roof Bars etc. are checked to determine the overall feasibility of the proposed roof assembly. Suitable lateral and vertical support must be provided within the window/wall structure. Liniar **can not** accept responsibility for the overall stability of the conservatory, unless a portal frame structure is supplied (by others).

When designing a conservatory, careful consideration must be made on the overall stability of the structure that you wish to create. Some roof styles can inadvertently create an unstable structure that has no vertical support at the end of the ridge and may therefore allow potential movement. This is particularly relevant to box gutter applications if a gable fronted roof style is incorporated into the design, please contact the Liniar's Technical Department as your roof maybe unstable. Any unstable roof design **must** be installed with a portal frame supporting structure.

Please note only conservatories up to 30m² floor area are **exempt** from Building Regulation approval.

Any designs requiring structural calculations or portal frame structures must be performed by a qualified structural engineer, we do not provide this service and additional charges will be incurred.

Please contact Liniar's Technical Department for guidance on Lantern roof styles

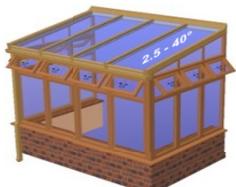

Contents...

1	Guidance	7	Victorian Hips (Duopitch)
2	Environmental Loadings	8	Gable Fronts (Duopitch)
3	Transom Bars (Monopitch)	9	Valleys (Combination Roofs)
4	Hipped Bars (Monopitch)	10	Unsupported Eaves
5	Transom Bars (Duopitch)	11	Tie-Bars
6	Edwardian Hips (Duopitch)	12	Structural Supports

1.1 - Guidance ...

Monopitch Roof Pitch Range...

Standard Lean-To's

Hipped Lean-To's

Wallplate Pitch Range : **2.5° to 14°**
Half Ridge Pitch Range : **15° to 40°**

Min pitch
for a Hipped
Lean-To : 5°

Duopitch Roof Pitch Range...

Edwardian's

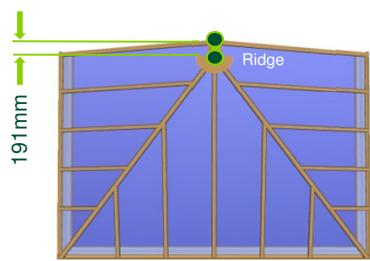

Victorian's

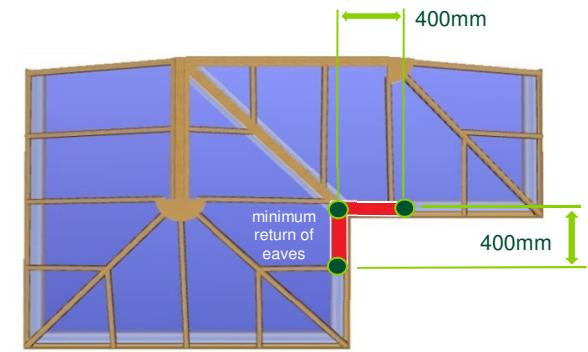

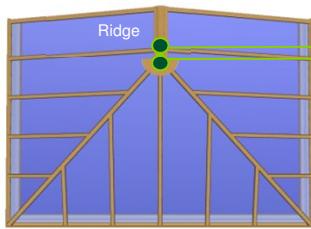

Gable Front's

Ridge Pitch Range : **15° to 40°**

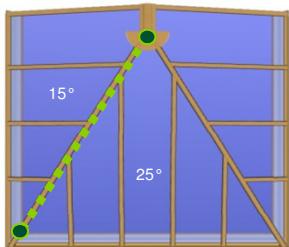

Limitations ...

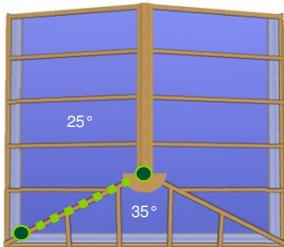

The minimum length of ridge for a duopitch roof is **191mm**, any ridge greater should extend beyond the first set of rafters by a minimum of **90mm**

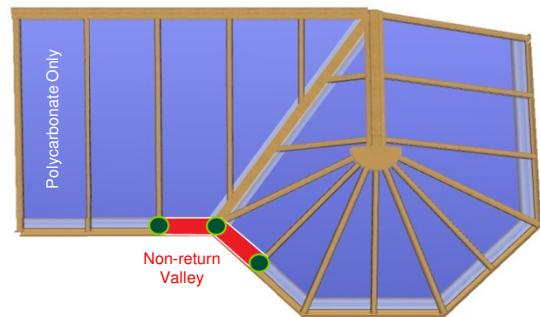

The minimum length of the supporting eaves beam should be no less than **400mm**

The maximum pitch differential over a hip bar should be no greater than **10°**, this rule applies to hipped roof styles

A minimum ridge length of **380mm** should be applied to double hipped roofs and must have at least one set of rafters to support the ridge

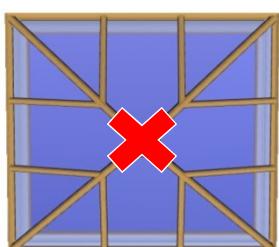

If the style constitutes a non-return valley (Victorian facets) assembly, the design will be only made available in **POLYCARBONATE** glazing and **WILL NOT be supplied in Glass**

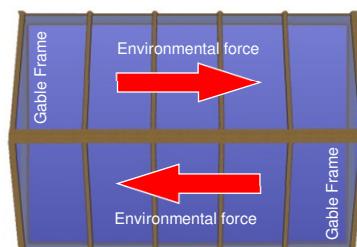

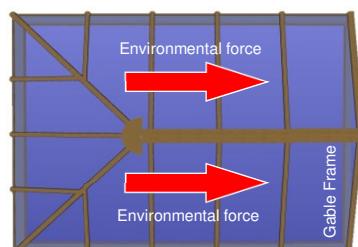

See section 9 for maximum valley lengths

Unsuitable applications ...

We regret Gazebo styles will be unavailable until further notice

Please check the feasibility of the conservatory before proceeding

Gable fronted styles without a supporting host wall are deemed unstable, they unable to withstand environmental forces acting on the gable ends and will allow movement of the ridge. These styles will only be made available if a supporting portal frame is specified

1.2 - How to use the guide

We have presented loading information into a series of tables, illustrating the span capabilities of your individual roof pitch and rafter/roof bar spacing's. It is essential that when you are assessing the feasibility of a conservatory structure all load bearing elements are checked for suitability

Step 1 : Environmental Loadings ...

There are many factors that need to be considered when assessing the feasibility of a conservatory roof layout. The first step of any conservatory design is to define the Environmental Loadings for the specific site installation.

We have collated typical geographical data for the majority of UK based cities and tabulated this information in Section 2 of this guide. Basic Snow Loading values are determined from the regional map, where loadings above 0.6 Kn/m² are shown in grey shade. Consult the Liniar Roof Technical Department regarding regions greater than 0.8 Kn/m².

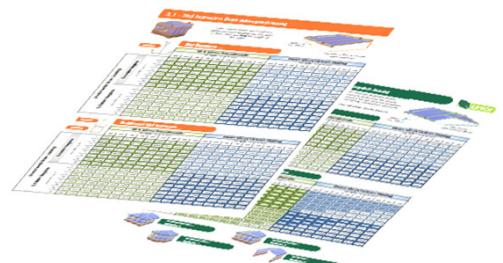

see Section 2 for Environmental Loading

Step 2 : Transom Bars ...

The Transom bar loading capabilities are dependent on the style of the roof.

Section 3 of this guide has been allocated for Monopitch (Lean-to) style roofs, illustrating how far they travel in plan for a single span. Whilst Section 5 has been allocated for Duopitch (with a Ridge) style roofs, illustrating how far they travel in plan for a double span. Having determined the environmental loading requirements in Step 1, use the look up charts to determine the loading capabilities of the proposed roof bar. Simply determine the intended glazing material, along with the proposed roof pitch and intended rafter.

see Section 3 for Monopitch bars

see Section 5 for Duopitch bars

Step 3 : Remaining Bars ...

The overall span of the conservatory is not determined solely on the performance of the Transom bars, this is determined mainly by the style of a roof. Allowable deflection limits on Hip Bars will reduce the span of a Georgian roof whilst the addition and contribution of imposed wind loadings will have an influence on a Gable Fronted configuration. Please refer to the relevant configuration elements in Section 4 and Section's 6 to 8 of this guide. Again, all information is detailed and defined by the glazing material, loadings and roof pitches.

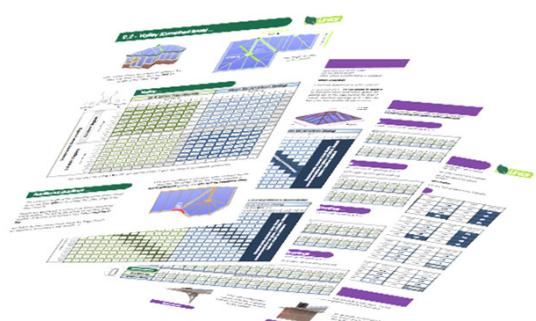

see Section 4 for Monopitch bars

see Section's 6 to 8 for Duopitch bars

Step 4 : Load Bearing Elements ...

The remaining sections within this guidance document covers Tie Bar requirements, Valley span checks, Eaves Beam Spans & Load Bearing Capacities of the proposed bay pole product range (check with the wall/window frame supplier).

see Section 9 for Valleys

see Section10 for unsupported Eaves

see Section 11 for Tie-bars

see Section 12 for Structural Supports

2.1 - Environmental Loadings

4.1 - Hipped Lean-To Bars (Monopitch Roofs)

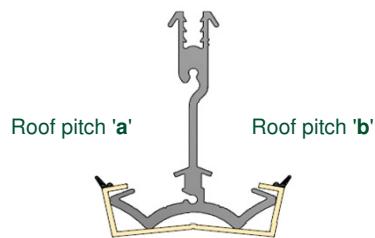

Note: Should the maximum span of the conservatory equal or exceed 6000mm (5200mm for Edwardian in glass), a portal frame structure must be installed (Please consult a Structural Engineer for further guidance). Values shown are maximum distances the valley can span in PLAN, they are NOT the length of the valley!

$$\text{Max length of hip in plan (L)} = \sqrt{(S^2+P^2)}$$

Maximum pitch differential = 9°

Maximum roof pitch (a & b) = 40°

Minimum roof pitch for Monopitch = 5°

Minimum roof pitch for Duopitch = 15°

Hip Length in plan ...

Max length of hip in plan =

$$\text{Length} = \sqrt{(\text{Span}^2 + \text{Projection}^2)}$$

or $\text{Length} = (\text{Span} / \sin c^\circ)$

or $\text{Length} = (\text{Projection} / \cos c^\circ)$

Angle c in plan ...

Angle of hip in plan view =

$$\tan c^\circ = (\text{Span} / \text{Projection})$$

Span (roof a) ...

Span (to half D-Ring) =

$$\text{Span} = \sqrt{(\text{Length}^2 - \text{Projection}^2)}$$

or $\text{Span} = (\text{Length} * \sin c^\circ)$

or $\text{Span} = (\text{Projection} * \tan c^\circ)$

Projection (roof b) ...

Projection =

$$\text{Projection} = \sqrt{(\text{Length}^2 - \text{Span}^2)}$$

or $\text{Projection} = (\text{Length} * \cos c^\circ)$

or $\text{Projection} = (\text{Span} / \tan c^\circ)$

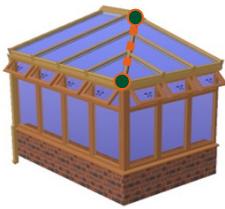

Angle 'c'	Roof pitch 'a' (for Monopitch roofs)							
	5°	10°	15°	20°	25°	30°	35°	40°
Roof pitch 'b' (for Monopitch's)	5°	45.00	63.61	71.92				
	10°	26.39	45.00	56.65	64.15			
	15°	18.08	33.35	45.00	53.64	60.12		
	20°		25.85	36.36	45.00	52.03	57.77

5.1 - Std Transom Bars (Duopitch Roofs)

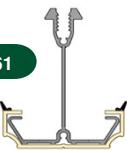

It should be noted that the capabilities of the Transom bars are illustrated below, however all loading bearing elements must be checked to determine the overall feasibility of the proposed roof assembly. This may reduce the size and the limitations of the conservatory, see relevant style sections and remaining component elements!

Note: Values shown are maximum span distances between Eaves Beams, they are **NOT** the length of the rafter!

5.3 - XHD Transom Bars (Duopitch Roofs)

It should be noted that the capabilities of the Transom bars are illustrated below, however all loading bearing elements must be checked to determine the overall feasibility of the proposed roof assembly. This may reduce the size and the limitations of the conservatory, see relevant style sections and remaining component elements!

Note: Values shown are maximum span distances between Eaves Beams, they are **NOT** the length of the rafter!

6.1 - Edwardian Hip Bars (Duopitch Roofs)

Note: Should the maximum span of a Edwardian conservatory with Polycarbonate equal or exceed 6000mm, or a Edwardian conservatory with Glass equal or exceed 5200mm, a portal frame structure must be installed. (Please consult a Structural Engineer for further guidance). Values shown are maximum internal width of the conservatory between Eaves Beams! Values shown have been based upon the assumption that are two or more Jack Rafters each side of the Hip Bar

Assuming Symmetrical Roof Pitches **a & b** (equal facet widths). For unequal pitches please see the maximum lengths of hip bars as detailed in section 4

9.1 - Valley (Combined Roofs) ...

Note: Should the maximum span of the conservatory equal or exceed 6000mm (5200mm for georgian in glass), a portal frame structure must be installed (Please consult a Structural Engineer for further guidance). Values shown are maximum distances the valley can span in PLAN, they are NOT the length of the valley!

Maximum roof pitch (**a & b**) = 35°

Minimum roof pitch for Monopitch = 5°

Minimum roof pitch for Duopitch = 15°

Valley Length in plan ...

Max length of valley =

$$\text{Length} = \sqrt{(\text{Span}^2 + \text{Projection}^2)}$$

$$\text{or } \text{Length} = (\text{Span} / \sin c^\circ)$$

$$\text{or } \text{Length} = (\text{Projection} / \cos c^\circ)$$

Angle **c** in plan ...

Angle of valley in plan view =

$$\tan c^\circ = (\text{Span} / \text{Projection})$$

Span (roof **a**) ...

Span (1/2 width of roof **a**) =

$$\text{Span} = \sqrt{(\text{Length}^2 - \text{Projection}^2)}$$

$$\text{or } \text{Span} = (\text{Length} * \sin c^\circ)$$

$$\text{or } \text{Span} = (\text{Projection} * \tan c^\circ)$$

Projection (roof **b**) ...

Projection (roof **b**) =

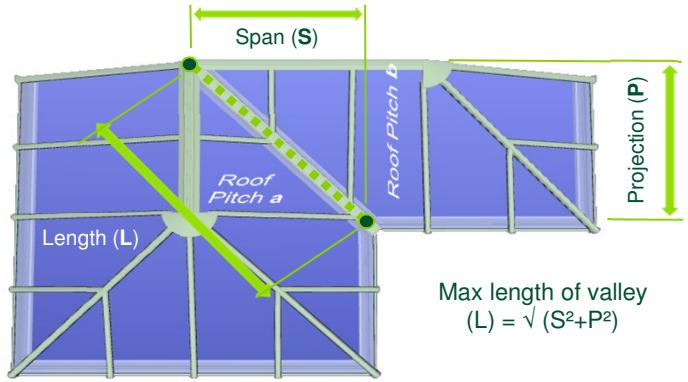

$$\text{Projection} = \sqrt{(\text{Length}^2 - \text{Span}^2)}$$

$$\text{or } \text{Projection} = (\text{Length} * \cos c^\circ)$$

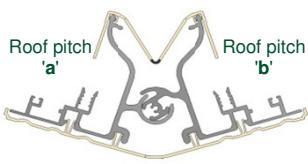

$$\text{or } \text{Projection} = (\text{Span} / \tan c^\circ)$$

Angle 'c'	Roof pitch 'a' (for Monopitch roofs)							
	5°	10°	Roof pitch 'a' (for Duopitch roofs)

The max pitch for roof a & b is 35°, any pitches shown in grey are beyond acceptable parameters

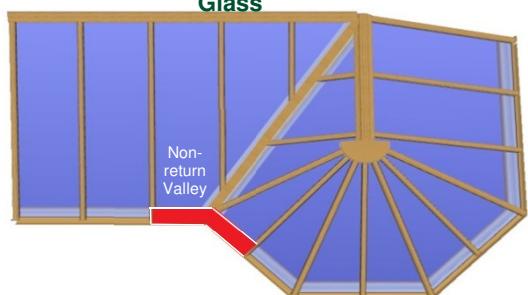

Additional guidelines ...

The minimum length of the supporting eaves beam should be no less than 350mm to enable the valley wings to be sited correctly.

Position the glazing bar a minimum of 90mm behind the D-Ring (Radius). The first Tie-Bar should be located at this position. All tie-bars and Transom/Jack Rafters **must be in-line**.

Any further tie-bars requirements along the Ridge should be applied in accordance with Section 10

If the style constitutes a non-return valley (Victorian facets) assembly, the design will be only made available in **POLYCARBONATE** glazing and **WILL NOT be supplied in Glass**

10.1 - Tie Bar Guidelines ...

Suitable lateral & vertical support must be provided within wall/window structure at the edge of the opening by the conservatory designer/retailer to support the Eaves Beam
Liniar Roof's can not accept responsibility for the overall stability of the conservatory unless a portal frame is supplied

TIE BARS DO NOT OFFER ANY RESISTANCE TO LATERAL WIND LOADING

Tie-Bar info provided with this guide is for Liniar roofs where...

The conservatory is fixed to a host wall of suitable construction.

Standard eaves beams/box gutters are used at a common level & the roof is symmetrical.

The roof angle is between 25°- 40° or 15° - 40° when tie bars are required.

Structural openings up to 1.85m are required.

The first tie-bar is in line with the first glazing bar on the ridge behind the finial, if required. If more tie bars are required spacings tie bar/tie bar and tie bar/wall should be equal.

Standard tie bar to transom bar and corner connections are used.

Tie bars should be correctly installed before glazing material & never more than 2.4m from another tie bar or corner joint/wall.

Fabricated special box gutters are not included in the design of the conservatory, if required contact the Zoom Technical Department for tie bar positions and special box gutter reinforcement details.

See specific notes for different roof styles.

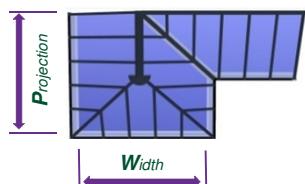

The snow load is less than 0.8kN/m², see Snow Load Map in section 2.1

For additional information on structural stability please refer to the Glass & Glazing Federation's glazing manual data sheet 5.7.10.

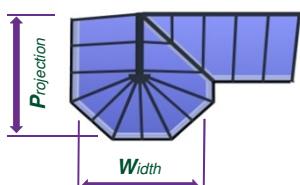

Combined Roofs - max dim's before Tie-Bars are required ...

Tie-Bars are required in these basic designs when the dimensions illustrated (in mm's) are exceeded.

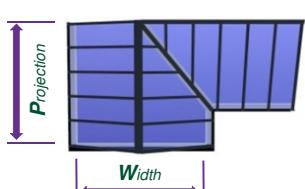

Most combination roofs will require Tie-Bars

Edwardian's ...

Victorian's ...

Gable's ...

Refer to section 10.2

	Projection	Width
25 & 32mm Polycarbonate	3500	3250

25 & 32mm Polycarbonate	3250	3250
24mm IGU (4/16/4mm Glazing)	3000	3250

10.2 - Tie Bars (Edwardian Roofs)

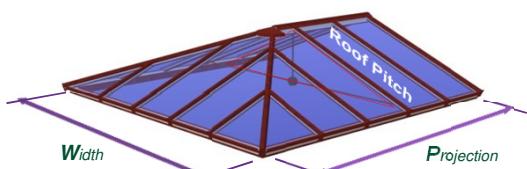

Suitable lateral & vertical support must be provided within wall/window structure at the edge of the opening by the conservatory designer/retailer to support the Eaves Beam
Liniar Roof's can not accept responsibility for the overall stability of the conservatory unless a portal frame is supplied

TIE BARS DO NOT OFFER ANY RESISTANCE TO LATERAL WIND LOADING

Recommendations for snow loading regions less than 0.8kN/m², please contact Liniar Roof's Technical Department for further guidance

The tables below detail the minimum Tie-Bar requirements based on the width, projection and roof pitch. **It is necessary to apply a Tie bar for all Edwardian roofs below the default 25° pitch.** recommendations assume the standard eaves beams/box gutters are used at a common level & the roof is symmetrical. The first tie-bar is in line with the first glazing bar on the ridge behind the finial, if required. If more tie bars are required spacings tie bar/tie bar and tie bar/wall should be equal. Structural openings up to 1.85m are required. **Tie bars should be correctly installed before glazing material** and never more than 2.4m from another tie bar or corner joint/wall.

Requirements exceed Liniar Roof's recommendation for glass, a PORTAL FRAME System must be installed

10.3 - Tie Bars (Double Hipped Edwardian Roofs)

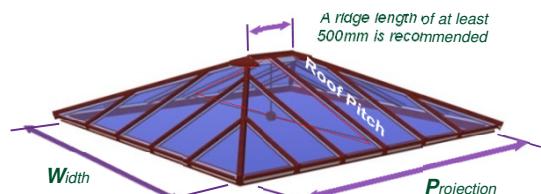

Suitable lateral & vertical support must be provided within wall/window structure at the edge of the opening by the conservatory designer/retailer to support the Eaves Beam
Liniar Roof's can not accept responsibility for the overall stability of the conservatory unless a portal frame is supplied

TIE BARS DO NOT OFFER ANY RESISTANCE TO LATERAL WIND LOADING

Recommendations for snow loading regions less than 0.8kN/m², please contact Liniar Roof's Technical Department for further guidance

The tables below detail the minimum Tie-Bar requirements based on the width, projection and roof pitch. **It is necessary to apply a Tie bar for all Edwardian roofs below the default 25° pitch.** recommendations assume the standard eaves beams/box gutters are used at a common level & the roof is symmetrical. The first tie-bar is in line with the first glazing bar on the ridge behind the finial, if required. If more tie bars are required spacings tie bar/tie bar and tie bar/wall should be equal. Structural openings up to 1.85m are required. **Tie bars should be correctly installed before glazing material** and never more than 2.4m from another tie bar or corner joint/wall.

Where a single set of rafters are located on the ridge one central tie bar is required. Where two or more sets are specified Tie-Bars should be positioned on the rafters next to the Radius/D-Ring, if required.

Hipped Victorian Roof pitches 25° or

Hipped Victorian Roof pitches less than 25°

A ridge length of at least 500mm is recommended

10.6 - Tie Bars (Gable Fronted Roofs)

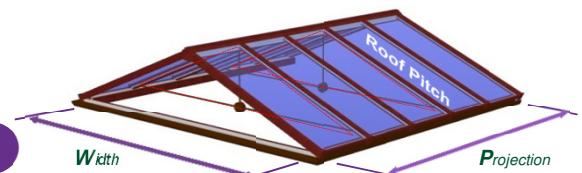

Suitable lateral & vertical support must be provided within wall/window structure at the edge of the opening by the conservatory designer/retailer to support the Eaves Beam
Liniar Roof's can not accept responsibility for the overall stability of the conservatory unless a portal frame is supplied

TIE BARS DO NOT OFFER ANY RESISTANCE TO LATERAL WIND LOADING

Recommendations for snow loading regions less than 0.8kN/m², please contact Liniar Roof's Technical Department for further guidance

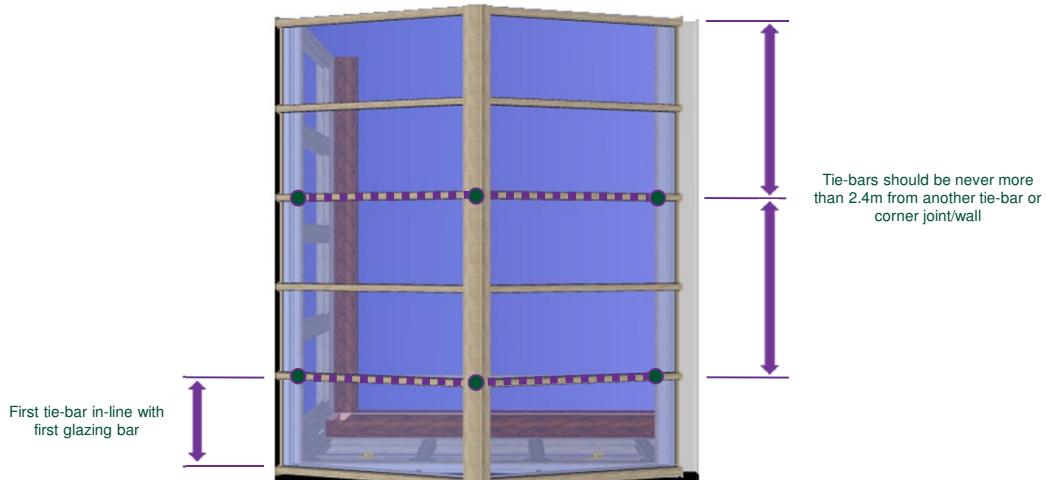

It is necessary to apply a Tie bar for all Gable Fronted roofs regardless of roof pitch. Based upon the standard eaves beams/box gutters are used at a common level & the roof is symmetrical. The first tie-bar is in line with the first glazing bar on the ridge behind the gable end. This can be ignored if the gable support connected by others can tie the eaves beams together and replace the first tie-bar. Structural openings up to 1.85m are required. **Tie bars should be correctly installed before glazing material** and never more than 2.4m from another tie bar or corner joint/wall.

Duopitch (Gable Fronts) Roofs - Partial Openings ...

Based upon the following assumptions: Imposed Load = 0.6 kN/m² with roof pitches up to 15°

Note: Eaves Beams in the Partial Opening must extend at least 1/5th beyond the support / start of the opening at both ends.
The total length of Eaves Beam must therefore be at least 1.4 x Partial Opening

12.1 - Structural Supports (Bay Poles) ...

The following 'load tables' have been calculated in accordance with the relevant BPF Code of Practice,
and are only applicable for joint profiles restrained at their centre

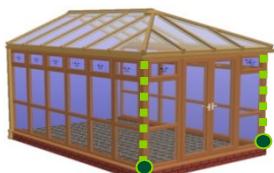

Liniar Roof's can not accept responsibility for the overall stability of the conservatory unless a portal frame is supplied

Suitable lateral & vertical support must be provided within wall/window structure at the edge of the opening
by the conservatory designer/retailer to support the eaves beam

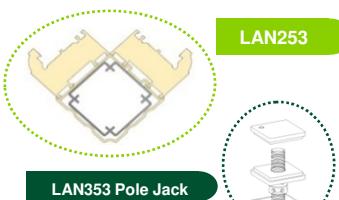

The load tables must not be applied to those joint profiles used in isolation

Key : N/A - The joint profile IS NOT suitable for load bearing situations at this length and above
Consult - The joint profile IS suitable for load bearing situations at this length and above, however please consult the Liniar Technical Department prior to fabrication

12.2 - Structural Supports (Mullions) ...

The following 'load tables' have been calculated in accordance with the relevant BPF Code of Practice, and are only applicable for joint profiles restrained at their centre

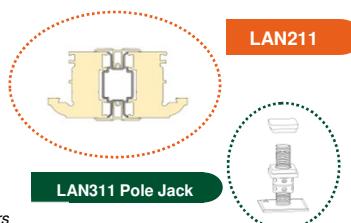

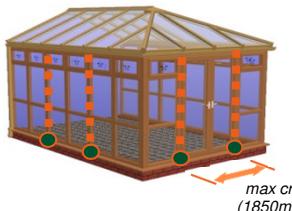

Liniar Roof's can not accept responsibility for the overall stability of the conservatory unless a portal frame is supplied

Suitable lateral & vertical support must be provided within wall/window structure at the edge of the opening by the conservatory designer/retailer to support the eaves beam

The load tables must not be applied to those joint profiles used in isolation

Key : N/A - The joint profile IS NOT suitable for load bearing situations at this length and above
Consult - The joint profile IS suitable for load bearing situations at this length and above, however please consult the Liniar Technical Department prior to fabrication

Structural Mullions...

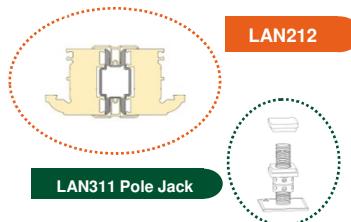

Length (mm)	Axial Load (Tonnes)	Length (mm)	Axial Load (Tonnes)	Length (mm)	Axial Load (Tonnes)
1100	1.79	1500	1.06	1900	N/A
1200	1.62	1600	0.94	2000	N/A
1300	1.38	1700	0.83	2100	N/A
1400	1.18	1800	N/A	2200	N/A

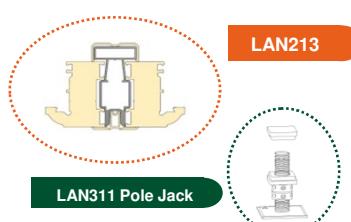

Structural mullions are required to provide vertical support for transferring roof loads from the eaves beam to the groundworks of the conservatory. This will prevent over stressing of the supporting window frames of the conservatory structure.

As a general rule Structural mullion spacings should be no greater than 1.85m ctrs unless loadings exceed the recommendations in Section 11 - Unsupported Eaves Beam Spans.

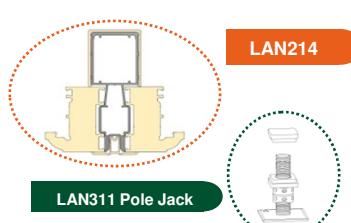

If in doubt, ask before proceeding !

Length (mm)	Axial Load (Tonnes)	Length (mm)	Axial Load (Tonnes)	Length (mm)	Axial Load (Tonnes)
1100	2.54	1500	1.43	1900	N/A

1400	2.62	1800	1.63	2200	Consult

Length (mm)	Axial Load (Tonnes)	Length (mm)	Axial Load (Tonnes)	Length (mm)	Axial Load (Tonnes)
1100	5.48	1500	4.76	1900	3.57
1200	5.39	1600	4.59	2000	3.36
1300	5.18	1700	4.33	2100	2.89
1400	4.97	1800	3.74	2200	Consult

12.3 - Structural Supports (Box Gutters) ...

The Box Gutter must be supported @ 2.25m Internvals along it's length, by means of either gallows brackets or brick piers. If a box gutter is supplied with an inline connector, additional support should be provided by means of gallows brackets or brick piers.

Gallows Brackets

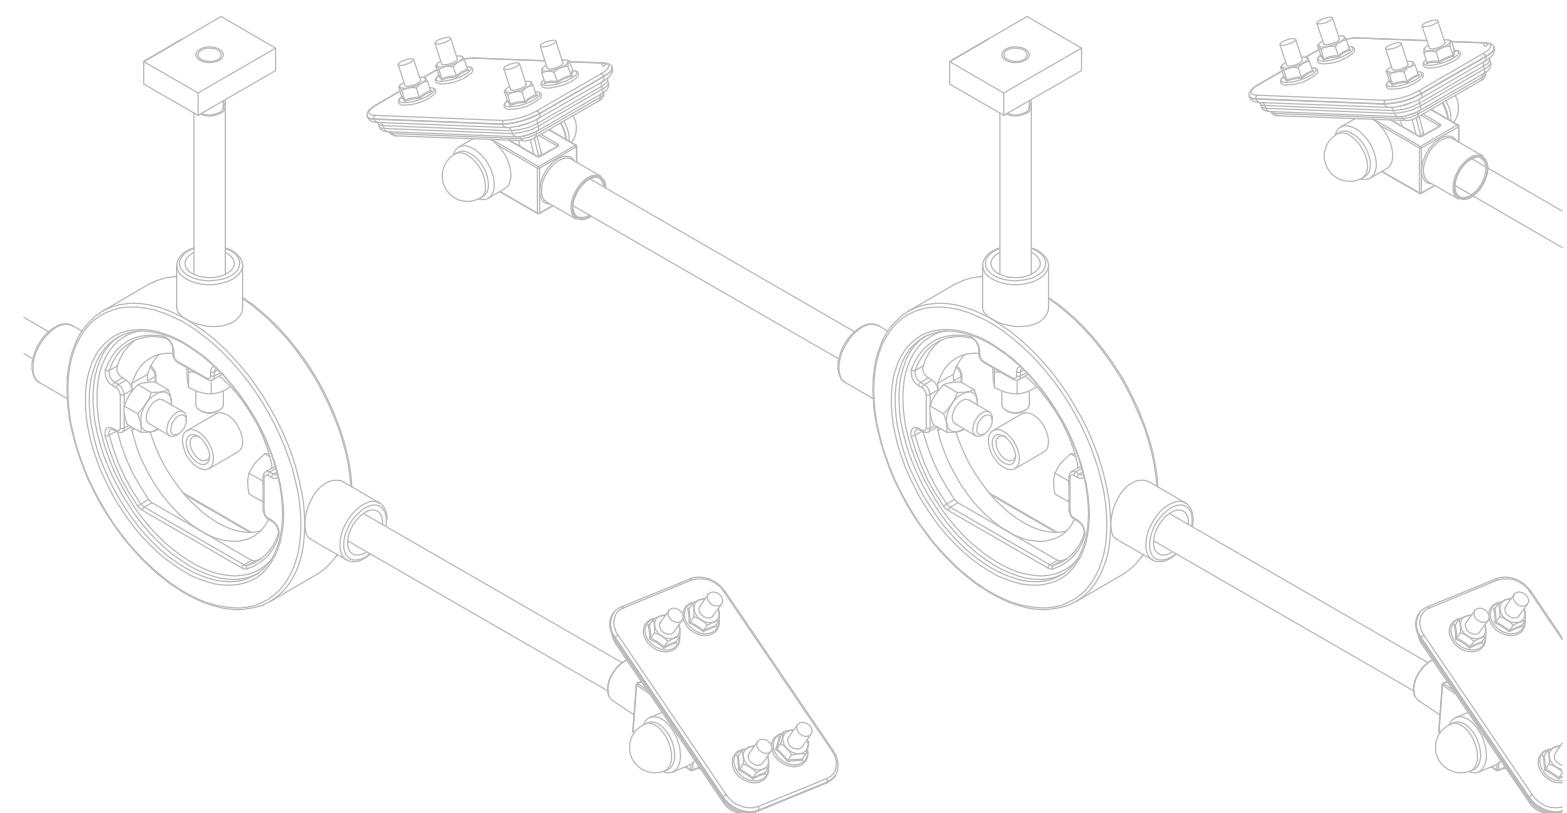

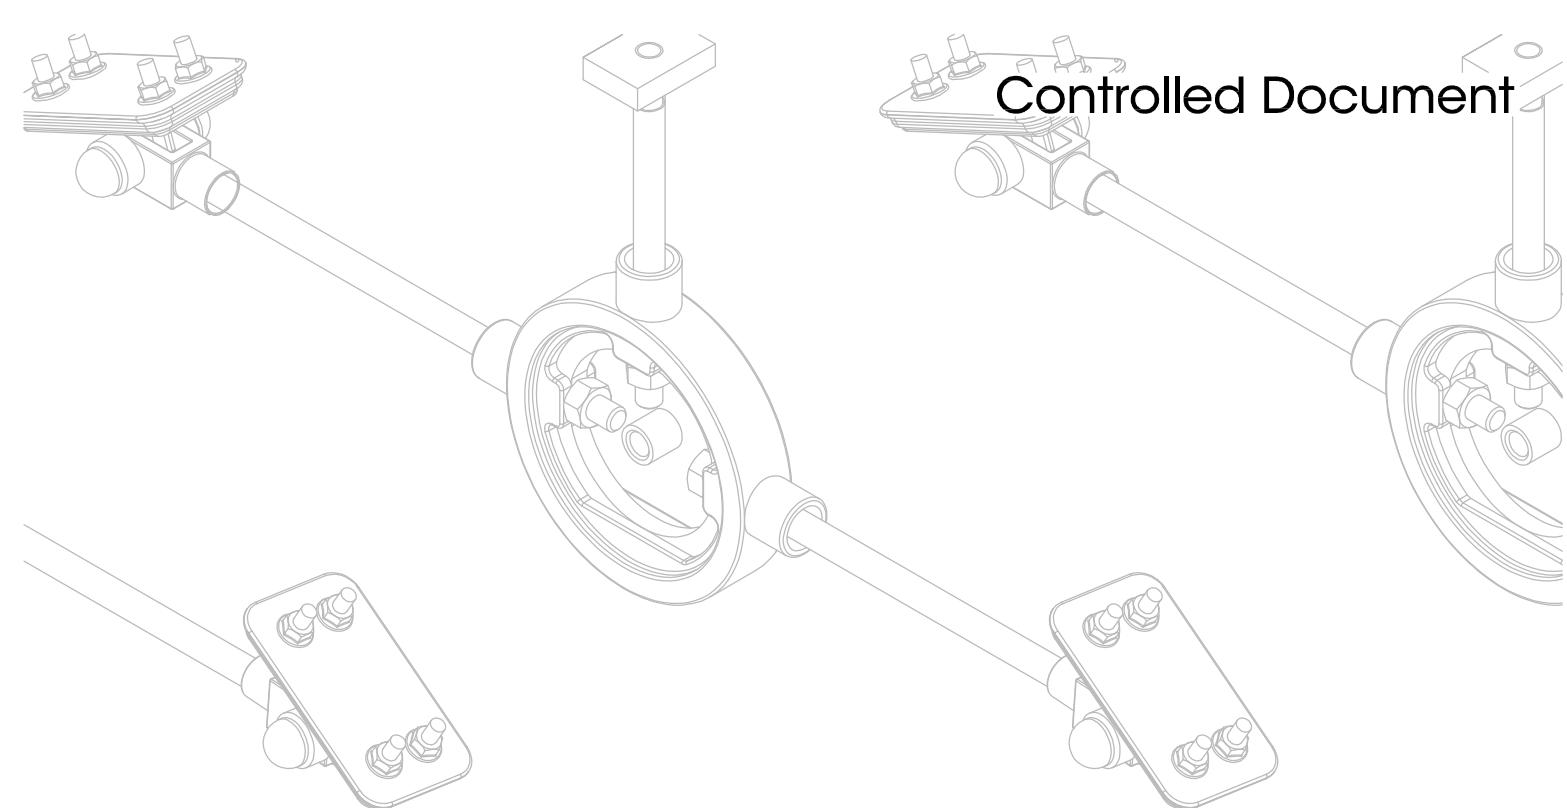

If the roof configuration requires a Tie-Bar, a gallows bracket must be sited at each Tie-Bar position.

Brick Piers

We generally recommend the use of brick pier to support the box gutter when it is fitted to soffits and fascias
